On-line Appendix for "Sharing the Pie: Undernutrition, Intra-household Allocation, and Poverty"

Caitlin Brown, Rossella Calvi, and Jacob Penglase

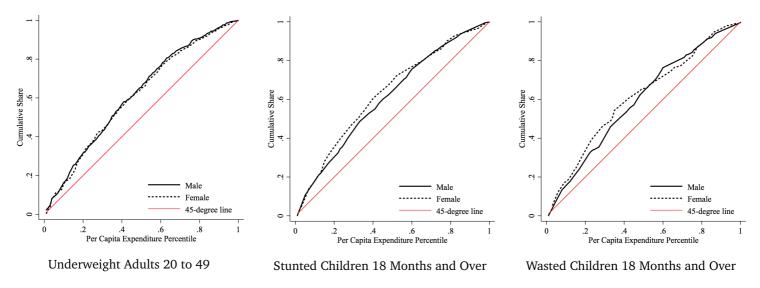

A Appendix

This Appendix contains eleven sections. Additional details and results on nutritional outcomes and food intake are discussed in Appendix A.1. In Appendix A.2 we discuss the quality of the 24-hour food recall survey and the possibility of measurement error. Our identification assumptions and theorems are presented in Appendix A.3; proofs are discussed in Appendix A.4. Appendix A.5 contains a graphical illustration of the D-SAP identification approach. In Appendix A.6, we discuss how we determine birth order from the information included in the Bangladesh Integrated Household Survey. In Appendix A.7, we provide tests of the preference restrictions required for identification and of Pareto efficiency of household allocations. In Appendix A.8 and Appendix A.9, we check the sensitivity of our poverty calculations to accounting for joint consumption and for individuals' activity levels, respectively. In Appendix A.10, we compare our model-based poverty calculations with those based on food shares. Additional figures and tables are in Appendix A.11.

A.1 Nutrition and Inequality: Additional Results

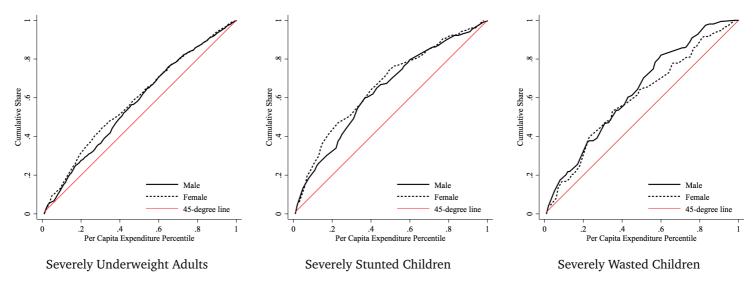

Potential Biases. Some potential biases could be influencing our findings regarding the link between household expenditure and individuals' nutritional outcomes (Section 3). The first is that the relatively weak relationship between household expenditure and undernutrition could be driven by excess mortality among the undernourished; that is, the sample may not include those who are too undernourished to survive. This is particularly true if excess mortality was concentrated among the poor. However, Boerma et al. (1992) report that the effect of survivorship bias on the estimates of child anthropometric indicators is marginal; Moradi (2010) also finds little evidence of such bias. Finally, Brown et al. (2018) simulate the potential effect of selective child mortality and find little difference in their results. Nonetheless, we acknowledge that the relationship between household expenditure and nutritional outcomes may be stronger if individuals who did not survive were to be included.

¹According to World Bank estimates, the mortality rate in Bangladesh for children under 5 in 2015 was 36.3 per 1000 live births (the average for South Asia was 50.3). Male children had a higher mortality rate (38.8) than female children (33.7).

Note: BIHS data. The graphs show concentration curves for the cumulative proportion of women and men aged 20 to 49 who are underweight, and children 18 months or older aged 0-5 who are stunted and wasted at each household per-capita expenditure percentile. Observations with missing values and pregnant or lactating women have been dropped. The Stata command glcurve is used to construct the curves.

Figure A1: Undernutrition Concentration Curves For the Restricted Sample (2015)

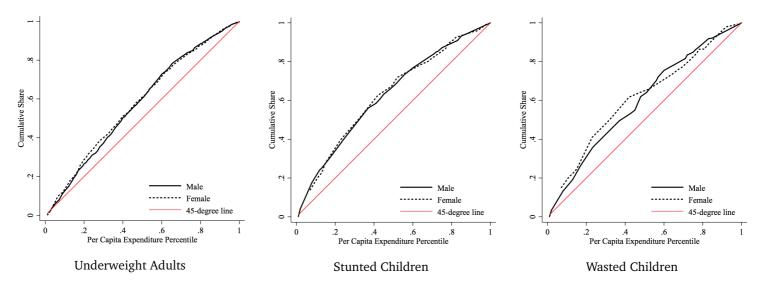

Note: BIHS data. The graphs show concentration curves for the cumulative proportion of adults aged 15 to 49 and children aged 0-5 who are severely undernourished at each household per-capita expenditure percentile. Severely underweight is defined as a BMI of 17 or lower. Severely stunted and wasted are defined as 3 SDs below the median for height-for-age and weight-for-height respectively. The Stata command glourve is used to construct the curves.

Figure A2: Undernutrition Concentration Curves For Severely Undernourished Individuals (2015)

Another possible bias is related to measurement error in the anthropometric outcomes, particularly among very young children. Larsen et al. (1999) and Agarwal et al. (2017), for instance, find evidence of misreporting of child age in DHS surveys, which impacts height-for-age z-scores. Larsen et al. (1999), however, find little resulting impact on estimated rates of stunting. Moreover, Ulijaszek and Kerr (1999) note that height and weight are least susceptible to measurement error, while Jamaiyah et al. (2010) concludes that height and weight measurements for children under 2 are reliable. Nevertheless, to account for potential measurement error in the stunting and wasting indicators, we construct concentration curves excluding children younger than 18 months. We also replicate our analysis excluding teenagers (who may still be growing) and older adults (who may be frail or ill, and difficult to measure). These concentration curves (shown in Figure A1) look very similar to those shown in Figure 1 in Section 3.

Children in Bangladesh may also be smaller on average than children in other regions, for ex-

Note: BIHS data. Individuals who report having lost weight due to illness in the past four weeks are excluded. The graphs show concentration curves for the cumulative proportion of women and men who are underweight, and children aged 0-5 who are stunted and wasted at each household per-capita expenditure percentile. Observations with missing values and pregnant or lactating women have been dropped. The Stata command glcurve is used to construct the curves.

Figure A3: Undernutrition Concentration Curves Excluding Sick Individuals (2015)

ample Africa, and the definition of stunting and wasting may be including children who are not undernourished. We also include concentration curves for severely stunted and wasted children, where severe stunting and wasting is defined as 3 standard deviations below the median heightfor-age and weight-for-height scores (see Figure A2). We see slightly more curvature for stunted children, but the curves for wasted children are not dissimilar from those in Figure 1. While it does seem that poorer households are more likely to contain severely undernourished children, we still find these children across the expenditure distribution. We do not think that the definition of stunting and wasting is necessarily inappropriate for Bangladesh or is driving the results found in Figure 1.

Finally, we construct concentration curves excluding individuals who report having lost weight due to illness in the past four weeks (see Figure A3). Particularly among children, we find a higher concentration of the undernourished in the poorer percentiles (that is, higher curvature). This suggests that health shocks may affect both poor and non-poor households and may partly responsible for some of the heterogeneity in nutritional outcomes across the expenditure distribution. That exposure to diseases plays a role is indisputable and to some extent reassuring. This, however, does not dismiss our analysis of intra-household consumption inequality. In effect, it might be the case that individuals are exposed to diseases exactly because they do not receive enough resources (or vice versa). Given the data at hand, it is hard to assess how illness and resource sharing interact. We leave the answer to this interesting question to future research.

MLD Decomposition. Mean Log Deviation (as discussed in Section 3) can be decomposed into between and within household inequality as follows:

$$\begin{split} MLD &= \ln \bar{c} - \frac{1}{N} \sum_{j=1}^{J} \sum_{i=1}^{N_{j}} \ln c_{ij} \\ &= \frac{1}{N} \sum_{j=1}^{J} N_{j} \ln \bar{c}_{j} - \frac{1}{N} \sum_{j=1}^{J} \sum_{i=1}^{N_{j}} \ln c_{ij} + \ln \bar{c} - \frac{1}{N} \sum_{j=1}^{J} N_{j} \ln \bar{c}_{j} \\ &= \frac{1}{N} \sum_{j=1}^{J} \left(N_{j} \ln \bar{c}_{j} - \sum_{i=1}^{N_{j}} \ln c_{ij} \right) + \frac{1}{N} \left(\sum_{j=1}^{J} N_{j} \ln \bar{c} - \sum_{j=1}^{J} N_{j} \ln \bar{c}_{j} \right) \\ &= \underbrace{\frac{1}{N} \sum_{j=1}^{J} \sum_{i=1}^{N_{j}} \ln \left(\frac{\bar{c}_{j}}{c_{ij}} \right)}_{\text{Within}} + \underbrace{\frac{1}{N} \sum_{j=1}^{J} N_{j} \ln \left(\frac{\bar{c}}{c_{j}} \right)}_{\text{Between}} \end{split}$$

where we assume that each individual i belongs to household j has a nutritional intake of $c_i j$. Each household has a total of N_j members and an average household nutritional intake of c_j . We also assume a total of J households and N individuals. The average of all individual nutritional intake is given by \bar{c} .

A.2 How Accurate is the Food Data?

Our study relies on the 24-hour food recall module in the BIHS. This data is central to our analysis and therefore its reliability deserves attention. In this section, we describe several aspects of the survey that were designed to ensure its accuracy. We also discuss recent work by D'Souza and Sharad (Forthcoming) who extensively analyze potentially biases within the BIHS food module. Lastly, we conduct several robustness checks of our own to determine the extent of any measurement error.

As discussed in Section 3, a female enumerator surveyed the woman in the household most responsible for preparing and distributing meals. All enumerators had prior experience collecting dietary intake data, including some in Bangladesh. The enumerator asked the respondents recipes, ingredient amounts, the source of the ingredients, as well as the amount of each meal allocated to each person in the household, including guests. The survey also accounted for leftover food and food given to animals. If any individual did not consume a meal, the enumerator found out why.

Several precautions were implemented by IFPRI to ensure the accuracy of the survey. First, households were asked if the previous day was a "special day", and if so, they were asked about the most recent typical day. In addition, no households were surveyed during Ramadan. Any households with large inconsistencies in the data were revisited to ensure no mistakes were made. Moreover, for the 2015 wave, 10 percent of households were resurveyed to analyze the consistency of the responses across visits, and the data suggest that they were. For example, the difference in individual food allocation shares across visits is within 3.5 percentage points for half of the revisit sample, and within 10 percentage points for 83 percent of the revisit sample.

Meals consumed outside the household are also included in the data. One might be worried

that these meals are particularly susceptible to measurement error. However, D'Souza and Sharad (Forthcoming) analyze differences in food allocation across households where no meals are consumed away from home, and those where some are, and find no qualitative differences. We conduct additional tests of our own to analyze the quality of the 24-hour food module. First, we compare the per-capita amount households spent on food derived from the 7-day household-level food expenditure module to the individual food consumption aggregate derived from the 24-hour consumption module. In terms of levels, we find a reasonably strong correlation of 0.62. We then determine whether households were being reordered in terms of total consumption across the two survey modules. We compute percentile ranks of household food expenditure for both recall periods and find a correlation between the ranks of 0.74.

We check the robustness of our model estimates along several dimensions. We test the sensitivity of our results to restricting the estimation sample to households where each household member had at least one meal at home during the recall day. Recall that in our main specification we exclude households where either all men, or all women, or all children did not consume any food. We find that our results are not only qualitatively, but also quantitively confirmed. In addition, for each household we compute this difference between food consumption from the 7-day expenditure module and from the 24-hour food consumption module. We estimate our model excluding those household that display the highest discrepancies (that is, the top 10 percent of the distribution of the difference). The estimated resource shares are very similar to our baseline results (under D-SAP, for example, the average shares equal 0.158, 0.148, 0.245, and 0.337 for boys, girls, women, and men, respectively), which is reassuring. The full set of estimates is available upon request.

To summarize, measurement error is likely present in our data, as it is in almost all survey data. We believe measurement error in our context is not too severe, given both the results of the above robustness checks and the results in D'Souza and Sharad (Forthcoming). Nonetheless, it is important to comment on how any measurement error would affect our results. If the measurement error in food recalls is random, that is, the respondent was not systematically underestimating the consumption of a certain type of person in the household, then we are quite confident our results are robust. The above discussion is focused on this type of measurement error. On the other hand, if there are cultural norms that lead women to claim their husband is well-fed, or that they treat their children equally, then that may bias our results. How worried should we be about cultural norms affecting the survey responses? The survey enumerators were aware of these biases and instructed on how to still elicit honest responses (D'Souza and Sharad, Forthcoming). Furthermore, while we cannot directly examine the extent of cultural and social norms affecting the interview process, we can examine whether the 24-hour food recall is consistent with the anthropometric data. We discuss this in Section 7 and find that the observed health measures do validate our structural results.

A.3 Theorems

The section provides the two main theorems of the paper. Both are extensions of Theorems 1 and 2 in Dunbar et al. (2013) (hereafter DLP), and therefore share much of the same content. The main differences are in the data requirements (we need more) and the assumptions (we need fewer). The key differences can be found in Assumptions A2['], A3['], B3[']. Otherwise, we follow DLP.

A.3.1 Theorem 1

Let j denote individual person types with $j \in \{1,...,J\}$. The Marshallian demand function for a person type j and good k is given by $h_j^k(p,y)$. Each individual chooses x_j to maximize their own utility function $U_j(x_j)$ subject to the budget constraint $p^{'}x_j = y$, where p is vector of prices and y is total expenditure. Denote the vector of demand functions as $h_j(p,y)$ for all goods k. Let the indirect utility function be given by $V_j(p,y) = U_j(h_j(p,y))$.

Let z_s denote the vector of goods purchased by a household of composition s, where the subscript s indexes the household types. Let σ_j denote the number of individuals of type j in the household. From Browning et al. (2013), we write the household's problem as follows:

$$\max_{x_1,...,x_J,z_s} = \tilde{U}[U_1(x_1),...,U_J(x_J),p/y]$$
such that $z_s = A_s \left[\sum_{j=1}^J \sigma_j x_j\right]$ and $y = z_s'p$

where A_s is a matrix that accounts for the sharing of goods within the household. From the household's problem we can derive household-level demand functions $H_s^k(p, y)$ for good k in a household of composition s:

$$z_{s}^{k} = H_{s}^{k}(p, y) = A_{s}^{k} \left[\sum_{j=1}^{J} h_{j}(A_{s}^{'}p, \eta_{js}y) \right]$$
 (A2)

where A_s^k denotes the row vector given by the k'th row of matrix A_s , and η_{js} is the resource share for a person of type j in a household of size s. Lastly, resource shares sum to one:

$$\sum_{i=1}^{J} \sigma_j \eta_{js} = 1 \tag{A3}$$

ASSUMPTION A1: Equations (A1), (A2), and (A3) hold, and resource shares are independent of household expenditure at low levels of household expenditure.

Definition: A good k is a private good if the Matrix A_s takes the value one in position k, k and has all other elements in row and column k equal to zero.

Definition: A good k is assignable if it only appears in one of the utility functions U_i .

ASSUMPTION A2 : Assume that the demand functions include at least 2 private, assignable goods, denoted as goods j^1 and j^2 for each person type.

DLP require a single assignable good for each person j. We differ in that we require at least 2 different goods for each person.

Let \tilde{p} be the price of the goods that are not both private and assignable. Let p_j^k be the prices of the private assignable goods, with $k \in \{1, 2\}$.

ASSUMPTION A3': For $j \in \{1,...,J\}$ let

$$V_{j}(p,y) = I(y \le y^{*}(p))\psi_{j} \left[\nu(\frac{y}{G_{j}(p)}) + F_{j}(p), \tilde{p} \right] + I(y > y^{*}(p))\Psi(y,p)$$
(A4)

where $F_j(p) = b_j(p_j^1 + p_j^2, \bar{p}, \tilde{p}) + e(p)$, and $y^*, \psi_j, \Psi, \nu, b_j e$, and G_j are functions with y^* is strictly positive, G_j is nonzero, differentiable, and homogenous of degree one. The function ν is differentiable and strictly monotonically increasing. The functions b_j and e are homogenous of degree 0. Lastly, Ψ and ψ are differentiable and strictly increasing in their first arguments, differentiable, and homogenous of degree zero in their remaining arguments.

This assumption differs from Assumption A3 in DLP in the function $F_j(p)$. DLP restrict $F_j(p)$ to not vary across people with $\partial F_j(p)/\partial p_j = \phi(p)$. Here, we allow $F_j(p)$ to vary across people in the function $b_j(\cdot)$. However, the way $F_j(p)$ varies across people is restricted to be the same across goods 1 and 2: $\partial b_j(\cdot)/\partial p_j^1 = \partial b_j(\cdot)/\partial p_j^2$. This holds since the prices for goods 1 and 2 enter $b_j(\cdot)$ in an additively separable way. The function e(p) does not vary across people.

We use Roy's Identity to derive individual-level demand functions for goods $k \in \{1, 2\}$:

• For
$$I(y>y^*)$$

$$h_j^k(y,p) = -\Big[\partial \Psi_j(y,p)/\partial p_j^k\Big]/\Big[\partial \Psi_j(y,p)/\partial y\Big]$$

• For $I(y \le y^*)$

$$h_{j}^{k}(p,y) = -\frac{\frac{\partial V_{j}(p,y)}{\partial p_{j}^{k}}}{\frac{\partial V_{j}(p,y)}{\partial y}}$$

$$= \frac{y}{G_{j}(p)} \frac{\partial G_{j}(p)}{\partial p_{j}^{k}} + \left(\frac{\partial b_{j}(p_{j}^{1} + p_{j}^{2}, \bar{p}, \tilde{p})}{\partial p_{j}^{k}} + \frac{\partial e(p)}{\partial p_{j}^{k}}\right) \frac{1}{\nu'(\frac{y}{G_{j}(p)})} G_{j}(p)$$

$$= \frac{y}{G_{j}(p)} \frac{\partial G_{j}(p)}{\partial p_{j}^{k}} + \left(\frac{\partial b_{j}(p_{j}^{1} + p_{j}^{2}, \bar{p}, \tilde{p})}{\partial p_{j}^{k}} + \frac{\partial e(p)}{\partial p_{j}^{k}}\right) \frac{1}{\nu'(\frac{y}{G_{j}(p)})} \frac{y}{y/G_{j}(p)}$$

$$= a_{j}^{k}(p)y + \left(\frac{\partial b_{j}(p_{j}^{1} + p_{j}^{2}, \bar{p}, \tilde{p})}{\partial p_{j}^{k}} + \frac{\partial e(p)}{\partial p_{j}^{k}}\right) g(\frac{y}{G_{j}(p)})y$$

For $I(y \le y^*)$, we can then write the household-level Engel curves for the private, assignable goods for $j \in \{1, ..., J\}$ in a given price regime p:

$$H_{js}^{k}(y) = a_{js}^{k} \eta_{js} y + \left(\tilde{b}_{js} + \tilde{e}_{s}^{k}\right) g_{s} \left(\frac{\eta_{js} y}{G_{js}}\right) \eta_{js} y \tag{A5}$$

ASSUMPTION A4: The function $g_s(y)$ is twice differentiable. Let $g_s'(y)$ and $g_s''(y)$ denote the first and second derivatives of $g_s(y)$. Either $\lim_{y\to 0} y^{\zeta} g_s''(y)/g_s'(y)$ is finite and nonzero for some constant $\zeta \neq 1$ or $g_s(y)$ is a polynomial in $\ln y$.

Theorem 1: Let Assumptions A1, A2, A3, and A4 hold. Assume the household-level Engel curves for the private assignable goods H_{js}^1 and H_{js}^2 are identified for $j \in \{1,...,J\}$. Then the resource shares η_{js} are identified for $j \in \{1,...,J\}$.

A.3.2 Theorem 2

Let \tilde{p} be the price of the goods that are not both private and assignable. Let p_j^k be the prices of the private assignable goods, with $k \in \{1,2\}$ and $j \in \{1,...,J\}$. Let \bar{p} be the price of the private goods that are not assignable.

ASSUMPTION B3': For $j \in \{1,...,J\}$ let

$$V_{j}(p,y) = I(y \le y^{*}(p))\psi_{j}\left[u_{j}\left(\frac{y}{G_{j}(p)}\right) + b_{j}(p_{j}^{1} + p_{j}^{2}, \bar{p}, \tilde{p}) + e_{j}(p_{j}^{1}, p_{j}^{2}, \bar{p}), \tilde{p}\right] + I(y > y^{*}(p))\Psi(y, p)$$
(A6)

where y^* , ψ_j , Ψ , u_j , b_j e, and G_j are functions with y^* is strictly positive, G_j is nonzero, differentiable, and homogenous of degree one. The function ν is differentiable and strictly monotonically increasing. The functions b_j and e are homogenous of degree 0. Lastly, Ψ and ψ are differentiable and strictly increasing in their first arguments, differentiable, and homogenous of degree zero in

their remaining arguments.

This assumption differs from Assumption B3 in DLP as follows: We replace $u_j(\frac{y}{G(\bar{p})},\frac{\bar{p}}{p_j})$ with $u_j(\frac{y}{G_j(p)}) + b_j(p_j^1 + p_j^2, \bar{p}, \tilde{p}) + e_j(p_j^1, p_j^2, \bar{p})$. The function $u_j(\cdot)$ is still restricted to not depend on the prices of shared goods, however, we have included the function $b_j(\cdot)$ which is allowed to depend on the prices of shared goods, and therefore varies across household size. However, the way in which $b_j(\cdot)$ varies across household size is restricted to be the same across goods 1 and 2: $\partial b_j(\cdot)/\partial p_j^1 = \partial b_j(\cdot)/\partial p_j^2$. This holds since the prices for goods 1 and 2 enter $b_j(\cdot)$ in an additively separable way. We use Roy's Identity to derive individual-level demand functions for goods $k \in \{1,2\}$:

• For $I(y>y^*)$ $h_j^k(y,p) = -\Big[\partial \Psi_j(y,p)/\partial p_j^k\Big]/\Big[\partial \Psi_j(y,p)/\partial y\Big]$

• For $I(y \le y^*)$

$$\begin{split} h_{j}^{k}(p,y) &= -\frac{\frac{\partial V_{j}(p,y)}{\partial p_{j}^{k}}}{\frac{\partial V_{j}(p,y)}{\partial y}} \\ &= \frac{u_{j}^{'}(\frac{y}{G_{j}(p)})\frac{y}{G_{j}(p)^{2}}\frac{\partial G_{j}(p)}{\partial p_{j}^{k}} + (\frac{\partial b_{j}(p_{j}^{1} + p_{j}^{2},\bar{p},\tilde{p})}{\partial p_{j}^{k}} + \frac{\partial e_{j}(p_{j}^{1} + p_{j}^{2},\bar{p})}{\partial p^{k})j})}{u_{j}^{'}(\frac{y}{G_{j}(p)})\frac{1}{G_{j}(\tilde{p})}} \\ &= \frac{y}{G_{j}(p)}\frac{\partial G_{j}(p)}{\partial p_{j}^{k}} + (\frac{\partial b_{j}(p_{j}^{1} + p_{j}^{2},\bar{p},\tilde{p})}{\partial p_{j}^{k}} + \frac{\partial e(p_{j}^{1},p_{j}^{2},\bar{p})}{\partial p_{j}^{k}}))\frac{1}{u_{j}^{'}(\frac{y}{G_{j}(p)})\frac{y}{y/G_{j}(p)}} \\ &= a_{j}^{k}(p)y + (\frac{\partial b_{j}(p_{j}^{1} + p_{j}^{2},\bar{p},\tilde{p})}{\partial p_{j}^{k}} + \frac{\partial e(p_{j}^{1},p_{j}^{2},\bar{p})}{\partial p_{j}^{k}})f_{j}(\frac{y}{G_{j}(p)})y \end{split}$$

For $I(y \le y^*)$, we can then write the household-level Engel curves for the private, assignable goods for $j \in \{1, ..., J\}$ in a given price regime p:

$$H_{js}^{k}(y) = a_{js}^{k} \eta_{js} y + \left(\tilde{b}_{js} + \tilde{e}_{j}^{k}\right) f_{j} \left(\frac{\eta_{js} y}{G_{js}}\right) \eta_{js} y \tag{A7}$$

We take the ratio of resource shares for person j across two different household types, which results in the following equation:

$$\frac{\eta_{j1}}{\eta_{js}} = \zeta_{js} \tag{A8}$$

for $j \in \{1, ..., J-1\}$ and $s \in \{2, ..., S\}$. In total, this results in (S-1)(J-1) equations. Moreover, in the proof we will use that resource shares sum to one to write the following system of equations:

$$\sum_{j=1}^{J-1} (\zeta_{js} - \zeta_{Js}) \eta_{js} = 1 - \zeta_{Js}$$
(A9)

for $s \in \{2, ..., S\}$. Equation (A9) results in S-1 equations.

We can stack the system of equations given by Equations (A8) and (A9). This results in a system of J(S-1) equations. In matrix form, let E be a $J(S-1) \times 1$ vector of η_{js} for $j \in \{1,...,J-1\}$ and $s \in \{1,...,S\}$ such that $\Omega \times E = B$, where Ω is a $J(S-1) \times J(S-1)$ matrix, and B is a $J(S-1) \times 1$ vector.

ASSUMPTION B4: The matrix Ω is finite and nonsingular, and $f_i(0) \neq 0$ for $j \in \{1,...,J\}$.

Theorem 2: Let Assumptions A1, A2, B3, and B4 hold. Assume there are $S \ge J$ household types. Assume the household-level Engel curves for the private assignable goods H^1_{js} and H^2_{js} are identified for $j \in \{1,...,J\}$. Then the resource shares η_{js} are identified for $j \in \{1,...,J\}$.

A.4 Proofs

A.4.1 Proof of Theorem 1

The proof will consist of two cases. In the first case, we assume g_s is not a polynomial of degree λ in logarithms. In the second case we assume that it is. Define

$$\tilde{h}_{js}^{k}(y) = \partial [H_{js}^{k}(y)/y]/\partial y = (\tilde{b}_{js} + \tilde{e}_{s}^{k})g_{s}'(\frac{\eta_{js}y}{G_{js}})\frac{\eta_{js}^{2}}{G_{js}}$$

$$\lambda_{s} = \lim_{\gamma \to 0} [y^{\zeta}g_{s}''(y)/g_{s}'(y)]^{\frac{1}{1-\zeta}}$$

Case 1: $\zeta \neq 1$

Then since $H_{js}^k(y)$ are identified, we can identify $\kappa_{js}^k(y)$ for $y \leq y^*$:

$$\begin{split} \kappa_{js}^{k}(y) = & \Big(y^{\zeta} \frac{\partial \tilde{h}_{js}^{k}(y) / \partial y}{\tilde{h}_{js}^{k}(y)} \Big)^{\frac{1}{1-\zeta}} \\ = & \Big((\frac{\eta_{js}}{G_{js}})^{-\zeta} (\frac{\eta_{js}y}{G_{js}})^{\zeta} \Big[(\tilde{b}_{js} + \tilde{e}_{s}^{k}) g_{s}^{"} (\frac{\eta_{js}y}{G_{js}}) \frac{\eta_{js}^{3}}{G_{js}^{2}} \Big] / \Big[(\tilde{b}_{js} + \tilde{e}_{s}^{k}) g_{s}^{'} (\frac{\eta_{js}y}{G_{js}}) \frac{\eta_{js}^{2}}{G_{js}^{2}} \Big] / \Big[(\tilde{b}_{js} + \tilde{e}_{s}^{k}) g_{s}^{'} (\frac{\eta_{js}y}{G_{js}}) \frac{\eta_{js}^{2}}{G_{js}^{2}} \Big] \Big)^{\frac{1}{1-\zeta}} \\ = & \frac{\eta_{js}}{G_{is}} \Big(y_{js}^{\zeta} \frac{g''(y)}{g'(y)} \Big)^{\frac{1}{1-\zeta}} \end{split}$$

Then we can define $\rho_{js}^1(y)$ and $\rho_{js}^2(y)$ by

$$\rho_{js}^{1}(y) = \frac{\tilde{h}_{js}^{1}(y/\kappa_{js}^{1}(0))}{\kappa_{js}^{1}(0)} = (\tilde{b}_{js} + \tilde{e}_{s}^{1})g_{s}'(\frac{y}{\lambda_{s}})\frac{\eta_{js}}{\lambda_{s}}$$
$$\rho_{js}^{2}(y) = \frac{\tilde{h}_{js}^{2}(y/\kappa_{js}^{2}(0))}{\kappa_{js}^{2}(0)} = (\tilde{b}_{js} + \tilde{e}_{s}^{2})g_{s}'(\frac{y}{\lambda_{s}})\frac{\eta_{js}}{\lambda_{s}}$$

Taking the difference of the above two equations, we derive the following expression similar to

DLP:

$$\rho_{js}^{2}(y) - \rho_{js}^{1}(y) = \hat{\rho}_{js}(y) = (\tilde{e}_{s}^{2} - \tilde{e}_{s}^{1})g_{s}'(\frac{y}{\lambda_{s}})\frac{\eta_{js}}{\lambda_{s}} = \phi_{s}\eta_{js}$$

Then since resource shares sum to one, we can identify resource shares as follows:

$$\eta_{js} = \frac{\hat{\rho}_{js}}{\sum_{j=1}^{J} \hat{\rho}_{js}}$$

Case 2: g_s is a polynomial of degree λ in logarithms.

$$g_s(\frac{\eta_{js}y}{G_{js}}) = \sum_{l=0}^{\lambda} \left(\ln\left(\frac{\eta_{js}}{G_{js}}\right) + \ln y \right)^l c_{sl}$$

for some constants c_{sl} . We can then identify

$$\tilde{\rho^{1}}_{js} = \frac{\partial^{\lambda} [H_{s}^{1}(y)/y]}{\partial (\ln y)^{\lambda}} = (\tilde{b}_{js} + \tilde{e}_{s}^{1}) d_{s\lambda}^{1} \eta_{js}$$

$$\tilde{\rho^{2}}_{js} = \frac{\partial^{\lambda} [H_{s}^{2}(y)/y]}{\partial (\ln y)^{\lambda}} = (\tilde{b}_{js} + \tilde{e}_{s}^{2}) d_{s\lambda}^{2} \eta_{js}$$

Taking the difference of the above two equations, we derive the following expression similar to DLP:

$$\tilde{\rho}_{js}^{2}(y) - \tilde{\rho}_{js}^{1}(y) = \hat{\rho}_{js}(y) = (\tilde{e}_{s}^{2}d_{s\lambda}^{2} - \tilde{e}_{s}^{1}d_{s\lambda}^{1})\eta_{js} = \phi_{s}\eta_{js}$$

Then since resource shares sum to one, we can identify resource shares as follows:

$$\eta_{js} = \frac{\hat{\rho}_{js}}{\sum_{i=1}^{J} \hat{\rho}_{is}}$$

A.4.2 Proof of Theorem 2

The household-level Engel curves for person $j \in \{1, ..., J\}$ and good k:

$$H_{js}^{k}(y) = a_{js}^{k} \eta_{js} y + \left(\tilde{b}_{js} + \tilde{e}_{j}^{k}\right) f_{j} \left(\frac{\eta_{js} y}{G_{js}}\right) \eta_{js} y$$

For each $j \in \{1,...,J\}$ take the difference of the Engel curves for private, assignable goods k = 1 and k = 2.

$$\tilde{H}_{js}(y) = H_{js}^2(y) - H_{js}^1(y) = \tilde{a}_{js}\eta_{js} + \tilde{e}_j\tilde{f}_j(\frac{\eta_{js}y}{G_{js}})\eta_{js}y$$

Let s and 1 be elements of S. Since the Engel curves are identified, we can identify ζ_{js} defined by $\zeta_{js} = \lim_{y \to 0} \tilde{H}_{j1}(y) / \tilde{H}_{js}(y)$ as follows for $j \in \{1, ..., J\}$ and $s \in \{2, ..., S\}$

$$\zeta_{js} = \frac{\tilde{e}_j \tilde{f}_j(0) \eta_{j1} y}{\tilde{e}_j \tilde{f}_j(0) \eta_{js} y} = \frac{\eta_{j1}}{\eta_{js}}$$
(A10)

Then since resource shares sum to one,

$$\sum_{j=1}^{J} \zeta_{js} \eta_{js} = \sum_{j=1}^{J} \eta_{j1} = 1$$

$$\sum_{j=1}^{J-1} \zeta_{js} \eta_{js} + \zeta_{Js} \left(1 - \sum_{j=1}^{J-1} \eta_{js} \right) = 1$$

$$\sum_{j=1}^{J-1} (\zeta_{js} - \zeta_{Js}) \eta_{js} = 1 - \zeta_{Js}$$
(A11)

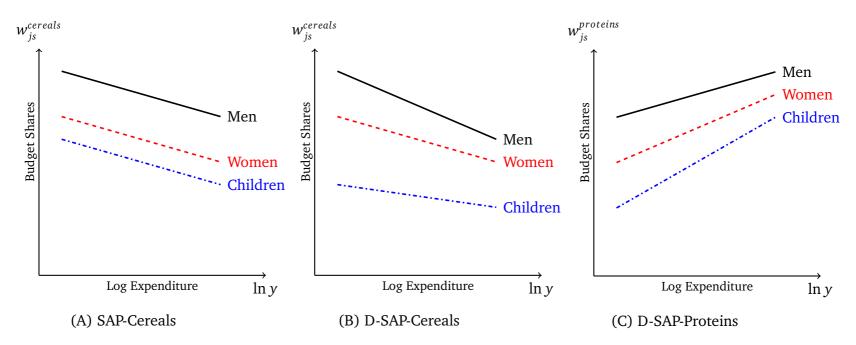

for $s \in \{2, ..., S\}$.

We then stack Equation (A10) for $j \in \{1,...,J-1\}$ and $s \in \{2,...,S\}$ and Equation (A11) for $s \in \{2,...,S\}$. This results in a system of J(S-1) equations. In matrix form, this can be written as the previously defined system of equations $\Omega \times E = B$, where E is a $J(S-1) \times 1$ vector of η_{js} for $j \in \{1,...,J-1\}$ and $s \in \{1,...,S\}$, Ω is a $J(S-1) \times J(S-1)$ matrix, and B is a $J(S-1) \times 1$ vector. By Assumption B4, Ω is nonsingular. It follows that for any given household type s, we can solve for J-1 of the η 's. Then since resource shares sum to one, we can solve for η_{Js} .

A.5 Graphical Illustration for D-SAP

To understand the D-SAP identification results graphically, we first plot hypothetical *individual-level* Engel curves for two assignable goods (e.g., cereals and proteins). Under SAP, DLP assume that preferences for one assignable good (either cereals or proteins) are similar across person types. With piglog preferences, this results in individual-level Engel curves with the same slopes as shown in Panel A of Figure A4.

We differ in that we allow allow preferences for the assignable goods to vary substantially across individuals. Panels B and C of Figure A4 illustrate this point as the slopes are no longer identical across people. However, we restrict preferences to differ across people in a similar way across goods. Intuitively, this means that if women have a higher marginal propensity to consume cereals than men, then they also have a higher marginal propensity to consume proteins than men. Under this assumption, if we difference the Engel curves we end up with Figure A5. Here, the differenced *individual-level* Engel curves are parallel, similar to SAP, and we can therefore use the DLP identification results to recover resource shares. In effect, any difference in the slopes of the *household-level* differenced Engel curves can be attributed to differences in resource shares, as in SAP.

Note: Individual-level Engel curves for assignable cereals and proteins. Figure (A) illustrates Engel curves under the SAP restriction (on cereals). The Engel curves in Figures (B) and (C) do not exhibit shape invariance, however, the difference in slopes across men, women, and children differ in the same way across goods.

 $w_{js}^{cereals} - w_{js}^{proteins}$ Men

Women

Children

Log Expenditure $\ln y$

Figure A4: SAP and D-SAP Comparison

<u>Note:</u> Differences in individual-level Engel curves across assignable cereals and proteins. The Engel curves are derived by taking the difference of Panels C and B from Figure A4. By assumption, the difference across Engel curves will have the same slope and we can therefore use the DLP identification results.

Figure A5: Differenced Engel Curves (D-SAP)

A.6 Determining Birth Order

To determine birth order, we begin by sorting children, grandchildren, and nephews and nieces by their age. This allows us to determine the *relative* birth order of children currently residing in the household. To determine the actual birth order this is not sufficient, since it is likely that for some households the first or second born children have already moved out. We use several different aspects of the survey to correct this measure.

First, the BIHS provides information on any household member who has left the household in

the previous five years. So, if we see that a child has moved out, we adjust the birth order of the children currently residing in the household to reflect this. Second, the BIHS does include birth order for children age zero to two in 2011, and also for children age zero to five in 2015. We combine this data with our existing "best guess" measure of birth order to again update the data. If we see that a child's stated birth order is one higher than our existing guess, we increase each child's birth order by one. We do this for children, grandchildren, and nephews and nieces separately. We are left with a measure of birth order that combines all the information available to us in the survey.

We also conduct our birth order analysis on a restricted sample where we expect less misclassification. We drop households with mother's who may have adult-age children who have left the household. Specifically, we estimate the model on households without mothers who are above age 35. The reason we choose 35 is that we assume the earliest a woman gives birth is 15, and that the earliest a child moves out is 15. Moreover, we know children who have migrated in the previous five years. It follows that we should be entirely accurate for women age 35 and under (15+15+5=35). Because women who are 35 in 2011 are 39 in 2015, we drop households with women above 39 in 2015. Results of this exercise are reported in Table A10.

A.7 Testing Model Assumptions

Preference Restrictions. As discussed in Section 4.2, distribution factors (i.e., variables that affect bargaining power but not individual preferences or the budget constraint) are not required for identification when using our novel strategies (D-SAP and D-SAT) as well as when using the methodologies developed by Dunbar et al. (2013) (SAP and SAT). Recent work by Dunbar et al. (2017), however, shows that when such variables are available the preference restrictions required for identification are no longer necessary. Specifically, if there are a sufficient number of distribution factors (or if there is a distribution factor with enough support points), if one maintains the assumption that resource shares not depend on total expenditures, and if one observes some assignable goods, then the level of resource shares can be identified. No similarity restrictions on tastes like those discussed in Section 4.2 are needed.

One limitation of this approach is that distribution factors may be difficult to find (especially when children are included in the model) and their validity (that they do not impact preferences or the budget constraint) might be hard to prove. Nonetheless, we here exploit this alternative approach to test the validity of the D-SAP, D-SAT, SAP, and SAT preference restrictions. Looking at the Engel curves for clothing, both Dunbar et al. (2017) and Calvi (2017) find evidence supporting the similarity across people assumption. In contrast, Bargain et al. (2018) mostly reject both SAP and SAT using observed individual-level Engel curves for several different assignable goods, including rice and protein. SAT with clothing, however, is not rejected by Bargain et al. (2018). Thus, we first apply the Dunbar et al. (2017) approach to estimate an unrestricted system of Engel curves of cereals and vegetables and then implement Wald tests for the similarity of preferences restrictions. For simplicity, we present tests for a model that comprises four types of individuals (women, men,

 $\underline{\text{Note:}}$ Estimates based on BIHS data, Engel curves for cereals and vegetables, and the Dunbar et al. (2017) identification approach.

boys, and girls).

Several recent studies have used relative unearned income or assets as distribution factors (see, e.g., LaFave and Thomas (2017); see Browning et al. (2014) for a discussion of the most widely used distribution factors in the literature). Conveniently, the BIHS data contains information about the ownership of assets, land, and animals. Based on this information, we construct three distribution factors capturing the share of such assets that is owned by women. By ranging between zero and one, these variables satisfy the requirement that the distribution factor must take on as many values as family member types. For example, if J = 4 (men, women, boys, girls), then a distribution factors that take on four values are enough. We also consider a fourth distribution factor computed as the first principal component of the other three.

The first panel of Table A1 contains the average resource shares for boys, girls, women, and men estimated using the Dunbar et al. (2017) approach and different distribution factors. It is reassuring to see that the estimates do not deviate significantly from the restricted models discussed in Section 5.2 (Table 4). In the second panel, we report the results of Wald tests for our preference restrictions. Interestingly, D-SAT and SAT are always rejected at conventional levels of significance. The SAP restriction on cereals preferences (preferences for vegetables are completely unrestricted) is rejected one out of four times, but the generally low p-values are not encouraging. By contrast,

the D-SAP restriction is never rejected at at conventional levels. We recall from Section 4.2 that D-SAP allows one's marginal propensity to consume cereals to differ considerably from other family members. However, it requires these differences to be similar to the difference in their preferences for vegetables.

Pareto Efficiency. Our model relies on the assumption that households achieve Pareto efficient allocations (if any household member can be made better off, someone else in the household must be worse off). In other words, we recognize that the allocation of resources within the household will depend on the members respective bargaining weights (therefore departing from unitary household models), but require that no matter how resources are allocated, none are left on the table. We now follow existing literature to provide a formal test of this assumption (Browning and Chiappori, 1998; Browning et al., 2014; LaFave and Thomas, 2017). As above, the test relies on the availability of distribution factors. Thus, similar caveats apply.

Recall from Section 4 that, under the assumption of efficiency, the optimization program can be rewritten as a two-stage process. In the first stage, the household may be treated as if all members pool their income and then re-allocate it among themselves according to some sharing rule. In the second stage, each household member maximizes her own utility given their income share. Under efficiency, distribution factors affect outcomes only through their impact on the first stage sharing rule. As a consequence, the ratio of e.g., the impact of men's assets to women's assets must be the same across outcomes. This property is known as *distribution factor proportionality*, and it is a sufficient condition for the collective model (Bourguignon et al., 2009).

We test this restriction empirically by estimating a set of linear regression models of the form:

$$W_i^k = \alpha^k + \beta_w^k y_i^w + \beta_m^k y_i^m + X_h' \gamma^k + \epsilon_i^k$$
(A12)

where W_i^k is a budget share for household i, and k is alternatively clothing, or men's, women's, or children's food. y_h^w and y_h^m are the share of household assets owned by women and by men, respectively. As some assets are jointly owned, y_h^w and y_h^m are not perfectly collinear. We use these variables as distribution factors. 2 X_h is a vector of household level characteristics (see Table A6).

If Pareto efficiency holds, then

$$\frac{\beta_w^k}{\beta_m^k} = \frac{\beta_w^j}{\beta_m^j} \quad \forall k \neq j. \tag{A13}$$

Table A2 reports the results of nonlinear Wald tests for equality of the ratios. We perform tests over our full estimation sample, and separately for nuclear and extended households. The null hypothesis of distribution factor proportionality (Pareto efficiency) cannot be rejected at any conventional levels of significance.

²Overall, distribution factors are jointly significant in all specifications. The p-values are below 0.10 for clothing, children's food, and women's food. The p-value equals 0.13 for men's food. These results provide a rejection of the unitary model, as it is inconsistent with the income pooling hypothesis. See Browning et al. (2014) for more details.

Table A2: Testing Pareto Efficiency

		Sample	
	All Households	Nuclear Only	Extended Only
	(1)	(2)	(3)
Test of equality of ratios between:			
1) Men's Food and Clothing Budget Shares Wald statistic p-value	0.12 0.7277	0.09 0.7701	0.89 0.3443
2) Men's Food, Women's Food, and Clothing Budget Shares Wald statistic p-value	1.35 0.5091	0.09 0.9580	1.78 0.4098
3) Men's Food, Women's Food, Children's Food, and Clothing Budget Shares Wald statistic p-value	1.94 0.5849	0.11 0.9907	1.87 0.5997

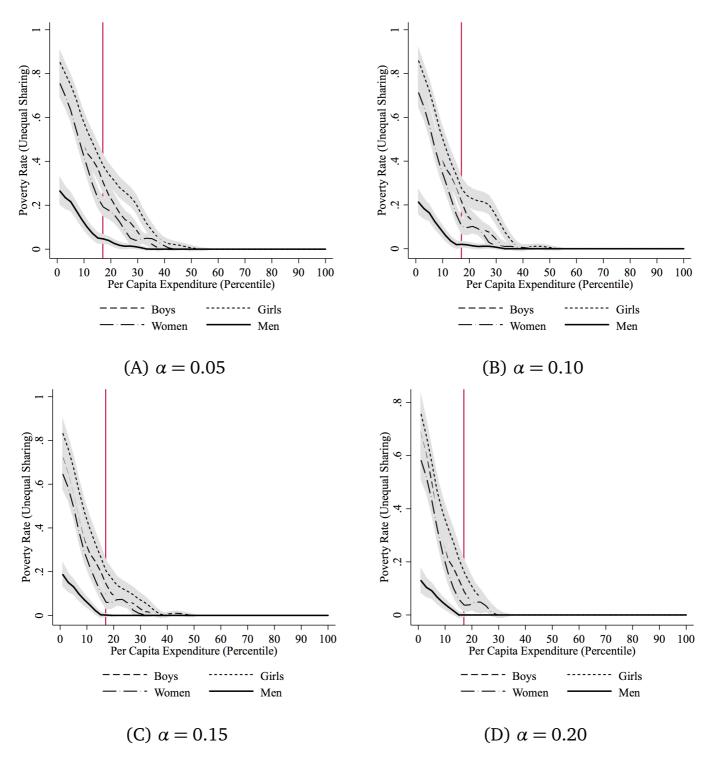

Note: Tests for proportionality restriction of the effects of distribution factors (share of women's assets and share of men's assets) across outcomes (Browning and Chiappori, 1998). The underlying regression models include the same household level controls as in Tables A6 and A7. Only households with one woman and one man are included in column 2. Only households with more than one woman and more than one man are included in column 3.

A.8 Economies of Scale and Joint Consumption

The theoretical model of household consumption presented in Section 4 does allow for economies of scale to consumption through a linear consumption technology function that transforms quantities purchased by the household in quantities consumed by each member. The structural parameters capturing the extent of joint consumption, however, are not estimated (this requires detailed price variation and substantially complicates the empirical exercise; see Browning et al. (2013) for details on point identification). Thus, in Section 6, we provide poverty calculations that ignore the existence and the extent of joint consumption (public and shared goods) in Bangladeshi families.

Deaton and Zaidi (2002) recommend low levels of scale economies in poor countries when incorporating joint consumption in poverty calculations (around 7 percent of the total budget): when the budget share of food is high, there is not much scope for economies of scale. We here consider varying levels of consumption jointness in the family by allowing the sum of individual resources to be larger than the observed total household expenditure. Four levels of consumption jointness are obtained by multiplying the household total expenditure by $(1 + \alpha)$, with $\alpha = 0.05, 0.1, 0.15, 0.2$.

Figure A6 shows the results of this analysis. Similarly to Figure 3, we display the fraction of individuals with an estimated level of individual consumption below the poverty line by household per-capita expenditure. For simplicity, we present results for year 2015 and obtained using the D-SAP approach. To account for differences in needs, we adjust the poverty lines for children and the elderly following the rough adjustment discussed in Section 6 (unadjusted poverty rates and rates obtained using a calorie-based adjustment are available upon request). Allowing for some degree of joint consumption has clear implications for our poverty calculations since it increases the amount of resources available to each individual. As we increase the extent of scale economies, poverty

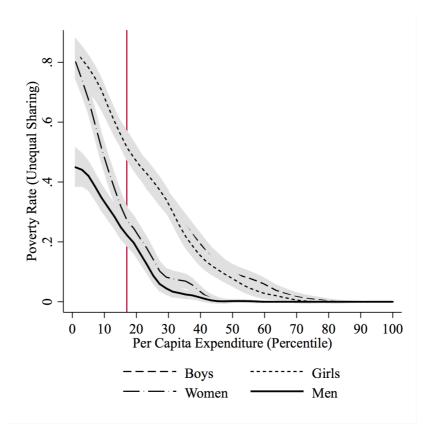

Note: Only households surveyed in 2015 are included. Individual consumption is obtained by multiplying total annual household expenditure (PPP dollars) by individual resource shares. The vertical line corresponds to the percentile of the \$1.90/day threshold. Estimates are based on BIHS data and D-SAP identification method with Engel curves for cereals and vegetables. In all panels, the poverty line for children (aged 14 or less) is set to 0.6*1.90 and the poverty line for the elderly (aged 46 plus) is set to 0.8*1.90. Three levels of consumption jointness are obtained by multiplying the household total expenditure by $(1 + \alpha)$, with $\alpha = 0.05, 0.1, 0.15, 0.2$.

Figure A6: Scale Economies and Joint Consumption

headcount ratios declines slightly. The relative poverty ranking for men, women, boys, and girls, however, is maintained.

A.9 Accounting for Individuals' Activity Levels

In Section 6, we adjust the \$1.90/day poverty line using relative caloric requirements to account for differences in needs by age and gender. In that exercise, however, we ignore possible differences in individuals' *activity levels*. Individuals who work in agriculture or construction may expend more energy on a day-to-day basis than individuals who live a more sedentary lifestyle. As a result, more

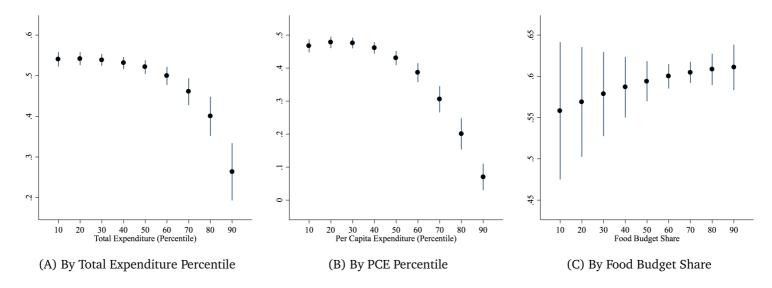

Note: Only households surveyed in 2015 are included. Individual consumption is obtained by multiplying total annual household expenditure (PPP dollars) by individual resource shares. The vertical line corresponds to the percentile of the \$1.90/day threshold. Estimates are based on BIHS data and D-SAP identification method with Engel curves for cereals and vegetables. We assume poverty lines to be proportional to their caloric requirements relative to young adults (aged 15-45) and we adjust them for the one's likely activity level. We rely on the daily calorie needs by age and gender estimated by the United States Department of Health and Human Services and assume that young adults that do not perform high-activity work require 2,400 calories per day. We classify individuals as high-activity if they work in a strenuous job (e.g., farming, construction, carpentry).

Figure A7: Poverty Rates Adjusted for Activity Levels

active individuals require more calories, and therefore more resources.

We modify our constructed individual-level poverty lines to account for differences in need by activity level. Using occupational data provided in the BIHS, we classify individuals as high-activity if they work in a strenuous job (e.g., farming, construction, carpentry). We consider an individual as employed in one of these occupations if they worked at least eight hours in the previous week in this job (the BIHS labor module is limited to a 7-day recall). In 2015, 47 percent of adult men worked in a high-activity occupation, whereas only 5 percent of women did. The USDA suggested caloric requirements specify thresholds for sedentary, moderately active, and active adults and children by age. For higher activity levels, the necessary calorie requirements increases by 200 to 400 calories per day. For simplicity we assume that individuals in high-activity occupations require 200 more calories per day than individuals not in those occupations.

Figure A7 presents poverty rates using this adjustment. A consequence of the adjustment is that, compared to the results presented in Section 6 (Figure 3), poverty rates for men increase slightly. No substantial difference, however, can be detected. It is important to note that this is a crude exercise that does not fully capture differences in needs. First, daily activity levels comprise much more than just employment. There are certain activities, such as fetching wood and fetching water, that require a significant amount of energy that we are unable to account for. These unaccounted for activities may have a gender component that affect the results presented above. Lastly, we

<u>Note:</u> BIHS data. The graphs show the marginal effects from logistic regressions (at different percentiles of total expenditure, per-capita expenditure and food budget share) of an indicator variable for being poor based on sharing of food on an indicator variable for being poor based on our model estimates of individual consumption.

Figure A8: Model-based Poverty vs. Food-based Poverty

only observe work in the previous week and therefore are not able to fully capture highly active individuals.

A.10 Poverty Rates Based on Individual Food Consumption

We here compare our poverty calculations (that are based on the estimated resource shares and are presented in Section 6) with calculations based on individual food shares. Using information on household food expenditure and individual food consumption, we construct individual food shares. We then compute an alternative measure of individual consumption as the product between these shares and a household's total expenditure. In other words, we assume that individuals consume non-food goods in the same proportion that they consume food. Since we are not imposing any inequality constraints when estimating the model, it is reassuring that only a very small fraction of individuals in our sample (less than 5 percent) have food consumption larger than our estimates of individual consumption (and that they are concentrated in households where food budget shares are high). These slight inconsistencies are likely due to estimation error and to the identification assumption that individuals in the same category are treated equally.

The resulting poverty rate is 38 percent, much higher than the poverty rates obtained with percapita expenditure (17 percent) or our estimates of individual consumption (27 percent). This higher rate could result from individuals in non-poor households consuming a low proportion of food but a high proportion of non-food goods.

The marginal effect from a logistic regression of the probability of having a food-based individual consumption below the poverty threshold on an indicator variable for being poor based on our model estimates equals 0.46 over the entire sample. We expect such association to be stronger in poorer households, where food represents a large portion of the total budget. We compute marginal effects at different percentiles of household expenditure (or for different values of food

budget shares) and find this to be the case (see Figure A8).³ These results are reassuring as they provide additional validation of our approach: our calculations are closer to the food-based ones exactly in households where food represents a large portion of overall consumption. However, they also suggest that in contexts with possibly high levels of intra-household inequality (where several poor people might reside in non-poor households) looking at food sharing alone is not enough.

A.11 Additional Tables and Figures

Table A3: BIHS Nutritional Outcomes

		2011			2015

Note: * p < 0.10, ** p < 0.05, *** p < 0.01. BIHS data. NLSUR estimates. Robust standard errors in parentheses. Age variables are divided by 100 to ease computation. We include indicators for the following regions: Barisal, Chittagong, Dhaka, Khulna, Rajshahi, Rangpur. Sylhet is the excluded region. None of the region indicators are statistically different from zero.

Note: $^{\circ}$ p < 0.10, ** p < 0.05, *** p < 0.01. BIHS data. NLSUR estimates. Robust standard errors in parentheses. Age variables are divided by 100 to ease computation. We include indicators for the following regions: Barisal, Chittagong, Dhaka, Khulna, Rajshahi, Rangpur. Sylhet is the excluded region. None of the region indicators are statistically different from zero. SAP and SAT restrictions are imposed on the first set of assignable goods (cereals), while the second set (vegetables) is unrestricted.

Table A8: Estimated Resource Shares - Reference Household

	D-SAP		D-SAT		S	AP	SAT		
	Estimate	Standard Error	Estimate	Standard Estimate Error		Standard Error	Estimate	Standard Error	
	(1)	(2)	(3)	(4)	(5)	(6)	(7)	(8)	
Boy	0.176	0.014	0.164	0.021	0.169	0.014	0.145	0.019	
Girl	0.1676	0.014	0.146	0.016	0.162	0.013	0.135	0.016	
Woman Man	0.2901 0.3662	0.014 0.018	0.273 0.417	0.036 0.033	0.296 0.373	0.014 0.018	0.308 0.413	0.038 0.033	

Note: Estimates based on BIHS data and Engel curves for cereals and proteins (meat, fish, dairy). The reference household is defined as one with 1 working man 15-45, 1 non-working woman 15-45, 1 boy 6-14, 1 girl 6-14, living rural northeastern Bangladesh (Sylhet division), surveyed in year 2015, with all other covariates at median values. SAP and SAT restrictions are imposed on the first set of assignable goods (cereals), while the second set (proteins) is unrestricted.

Table A9: Additional Results

			Resource Shares		Individual Consumption (PPP dollars)			
	Obs.	Mean	Median	St. Dev.	Mean	Median	St. Dev.	
-	(1)	(2)	(3)	(4)	(5)	(6)	(7)	
A) Young vs. older adults:								
Boys	4,502	0.130	0.142	0.037	668.85	593.67	333.91

Higher birth order boys	746	0.128	0.139	0.029	629.39	571.60	286.17	
Higher birth order girls	668	0.120	0.130	0.029	599.22	559.14	262.96	
Women	1,885	0.252	0.283	0.065	1,152.06	1,031.86	528.86	
Men	1,885	0.408	0.408	0.101	1,883.21	1,687.91	891.53	
C) Hhs. with first born girl:								
First born girl	1,804	0.146	0.148	0.019	703.85	628.71	322.39	
Higher birth order boys	775	0.142	0.155	0.034	726.79	639.89	367.50	
Higher birth order girls	768	0.132	0.145	0.034	666.18	590.75	332.97	
Women	1,804	0.233	0.261	0.060	1,097.46	961.25	546.05	
Men	1,804	0.405	0.408	0.113	1,914.54	1,669.56	962.87	

Note: Estimates based on BIHS data and D-SAP identification method with Engel curves for cereals and vegetables. Mean and median of resource shares do not need to sum to one because there can be more than one individual of the same type in each family. Individual consumption is obtained multiplying total annual household expenditure (PPP dollars) by individual resource shares.

Table A10: Additional Results - Restricted Samples

			Resource Shares			dual Consur PPP dollars	•
	Obs.	Mean	Median	St. Dev.	Mean	Median	St. Dev.

Observations λ	2,393 116.142	2,301 93.749	3,848 37.201	2,978 16.817

Note: OLS estimates. Regressions of an indicator variable for being poor based on estimated individual consumption on a series of characteristics and traits. Estimation samples include only individuals with per-capita expenditure above the poverty line and surveyed in 2015. Variables selected out of 43 variables for children, 54 variables for women, and 52 variables for men. Selection is made using lasso regularization. λ is the penalty parameter corresponding to the minimum BIC information criterion. Since lasso performs variable selection in a linear model, we report estimates for a linear probability model. Logistic regression estimates are available upon request.

Table A12: \mathbb{R}^2 for Estimated Individual Consumption and Per-Capita Consumption

		oric ake		tein ake		od mption	Under	weight	Stur	nting	Was	ting
	Ind.	PC	Ind.	PC	Ind.	PC	Ind.	PC	Ind.	PC	Ind.	PC

Girls	0.057	0.027	0.083	0.057	0.138	0.143			0.011	0.011	0.005	0.004

Note: BIHS data 2015. Adults are defined as 15 years and older. For the nutritional outcomes, children are 5 years and younger. For the nutritional intake variables, children are 14 years and younger. Nutritional intake variables are unscaled. Columns (1) to (6) report R^2 for linear regressions of food intake on estimated individual consumption (log) or per-capita consumption (log). Columns (7) to (12) report pseudo- R^2 for logistic regressions of nutritional status on estimated individual consumption (log) or percapita consumption (log). Regressions are run separately for estimated individual consumption and per-capita consumption. Odd-numbered columns refer to the estimated individual consumption (Ind.); even-numbered columns refer to per-capita consumption (PC).

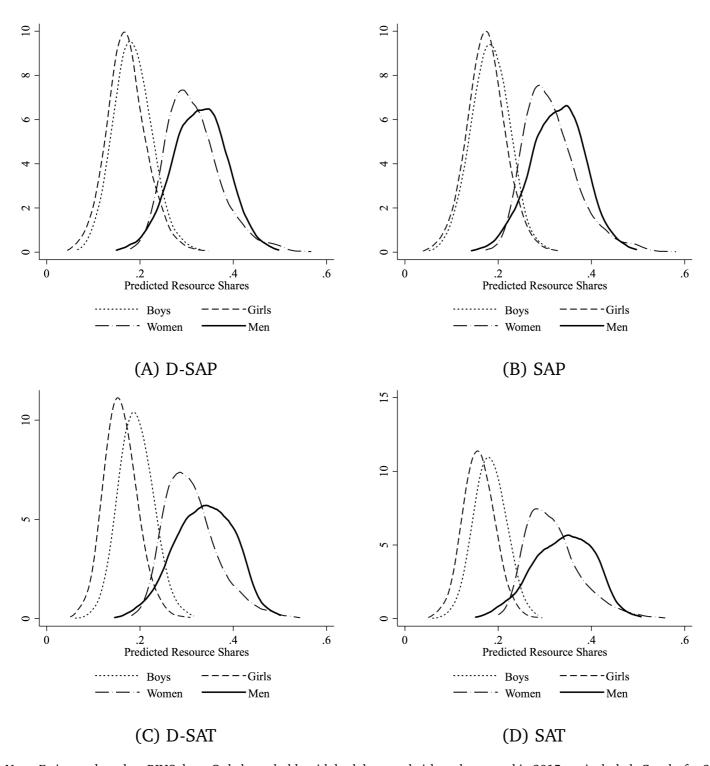

Note: BIHS data. The figure shows the rate of undernourishment within households by expenditure percentile, where a household member is defined as undernourished if he or she is underweight (for adults), stunted or wasted (for children). Adults are defined as 15 years and older; children as 5 years and younger. Households with no intra-household inequality in nutritional outcomes, i.e. those with either all nourished or undernourished members, are excluded.

Figure A9: Within Household Inequality in Nutritional Outcomes by Household Expenditure Percentile

Note: BIHS data. Proteins include meat, fish, milk, and eggs.

Figure A10: Non-Parametric Engel Curves

 $\underline{\text{Note:}}$ Estimates based on BIHS data. Only households with both boys and girls and surveyed in 2015 are included. Graphs for 2011 are similar and available upon request.

Figure A11: Estimated Resource Shares - Empirical Distributions (2015)

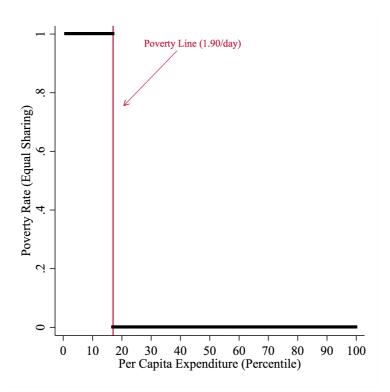

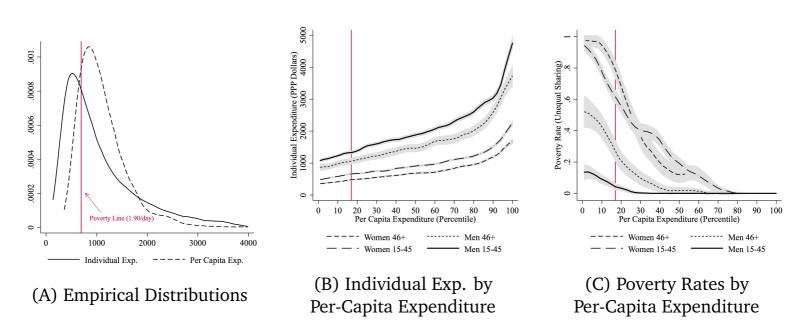

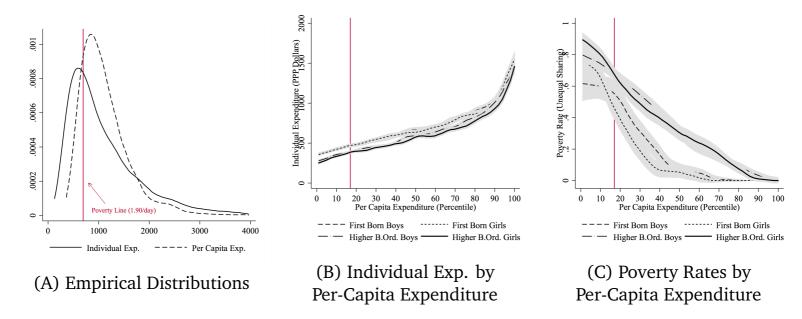

Figure A12: Poverty Rate by Per-Capita Expenditure Percentile

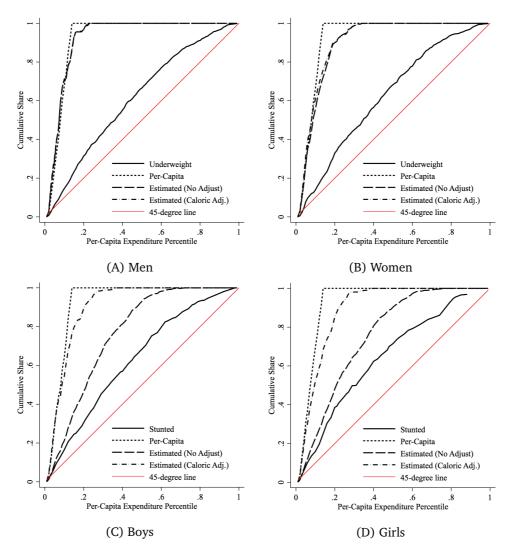

Note: Only households surveyed in 2015 are included. Individual consumption is obtained by multiplying total annual household expenditure (PPP dollars) by individual resource shares. The vertical line corresponds to the percentile of the \$1.90/day threshold. Estimates are based on BIHS data and D-SAP identification method with Engel curves for cereals and vegetables. In Panel C, we assume poverty lines for the elderly to be proportional to their caloric requirements relative to young adults (aged 15-45). We rely on the daily calorie needs by age and gender estimated by the United States Department of Health and Human Services and assume young adults require 2,400 calories per day.

Figure A13: Additional Results - Young vs. Older Adults

Note: Only households surveyed in 2015 are included. Individual consumption is obtained by multiplying total annual household expenditure (PPP dollars) by individual resource shares. The vertical line corresponds to the percentile of the \$1.90/day threshold. Estimates are based on BIHS data and D-SAP identification method with Engel curves for cereals and vegetables. In Panel C, we assume poverty lines for children to be proportional to their caloric requirements relative to young adults (aged 15-45). We rely on the daily calorie needs by age and gender estimated by the United States Department of Health and Human Services and assume young adults require 2,400 calories per day.

Figure A14: Additional Results - Birth Order

Note: BIHS data. Individuals who report having lost weight due to illness in the past four weeks are excluded. The graphs show concentration curves for the cumulative proportion of adults and children by gender who are undernourished and poor according to per-capita household consumption and estimated individual consumption, with no adjustment for differences in needs and adjusted for differences in caloric requirements. Individual consumption is estimated using the D-SAP approach and Engel curves for cereals and vegetables. Observations with missing values and pregnant or lactating women have been dropped. The Stata command glcurve is used to construct the curves.

Figure A15: Undernutrition and Individual Poverty Concentration Curves (2015)
